EMERALDS OF COLOMBIA

By Peter C. Keller

There has been more activity in emerald mining in Colombia in the last few years than at any other time in the four centuries since the Spanish first discovered the deposits. This article combines a comprehensive review of the literature on the history and geology of Colombian emeralds with the author's own insights into the current marketing and mining of these stones. Of particular concern are the harsh methods now being used to extract the emeralds and the impact these methods will have on future production in Colombia. The past, however, has yielded many fabulous gems, the most fabulous of which are also described here and placed in historical perspective.

ABOUT THE AUTHOR
Dr. Keller is director of education of the Gemological Institute of America, Santa Monica, CA.

Much of the research for this article was undertaken in preparation for a special exhibit of Colombian emeralds and pre-Columbian gold artifacts held at the Natural History Museum of Los Angeles County July 4–September 6, 1981. ©1981 Gemological Institute of America

Few gemstones on the world market today provide the aura of adventure and intrigue, wealth and beauty that is so intrinsic to emerald. The first records of emeralds worn as jewelry date from the early days of the Roman Empire, in reference to stones recovered from now long-lost Egyptian mines. They have been treasured as gems ever since. Although the Egyptian mines may have introduced emeralds to the Western world, historically the finest emeralds have come from deposits in Colombia. The checkered history of these mines began cruelly with the Spanish conquerors' enslavement of local Indians to work the deposits, leading to the decimation of the native population in just a few years. And as recently as the early 1970s, Muzo—the major mine—was forced to close because of over 900 emerald-related murders in one year.

Over the past half century, there have been numerous papers describing the status of the Colombian emerald mines, usually by recent visitors to the mining areas (MacFadden, 1934; Switzer, 1948; Copeland, 1950; Anderton, 1950 and 1965; Bancroft, 1971; and Tenhagen, 1972). However, few, if any, of these papers have combined their observations (which were usually on a single mine) with a comprehensive review of the literature to provide a detailed account of the history and geology of the emerald deposits. Furthermore, in the past five years we have seen more activity in the Colombian mines than there has been since the Spanish first exploited them in the 16th century. The purpose of this paper is to combine a comprehensive review of the literature with an update on current mining and marketing activity, based on several recent trips to the area by the author. In addition, major emeralds originally mined in Colombia and now

Emeralds of Colombia
housed throughout the world will be described, some for the first time.

OVERVIEW

There are two principal emerald-mining districts in Colombia today: Muzo and Chivor. The 360-km² Muzo district, at an elevation of about 600 m, is located 105 km north of the capital city of Bogota in the valley of the Rio Itoco, a tributary of the Rio Minero. The main mines in the Muzo district include the Tequendama, Santa Barbara, El Chulo, Coscuez, and Peñas Blancas (figure 1). The district is owned by the Colombian government and is currently being worked by several private mining companies operating under five-year leases (figure 2).

The Chivor district, located about 75 km northeast of Bogota in the Almeida township of Boyaca, is part of the exceedingly rugged country where the Rio Rucio and Rio Sinai join to form the Rio Guavio (figure 3). Feininger (1970) points out that the mine is at an elevation of about 2300 m and that just 2 km to the east, in sight of the mine, the Rio Guavio, at an elevation of only 700 m, slices through a ridge that is even higher than the mine (figure 4). In addition to the Chivor mine, the Chivor district includes the Buenavista mine, immediately to the south of Chivor, and the Las Vegas de San Juan mine, located 8 km to the southwest and commonly known as the...

Gachalá mine (Anderton, 1955). The Chivor mine is the only privately owned emerald mine in Colombia. The Buenavista and Gachalá mines operate as concessions under a 1959 law, and their owners pay a 25% royalty to the Colombian government (Colombian American Business, 1979).

There have been a number of studies on the geology of Muzo and, to a lesser extent, Chivor (see box). Our current knowledge of the geology tells us how the emeralds occur and where to direct future exploration. Thus far, however, a detailed study of the Eastern Cordillera has been inhibited by rugged terrain and thick vegetation, which has also restricted exploration.

**EARLY HISTORY**

Emeralds mined in Colombia have been used for trade and personal adornment throughout much of Middle and South America since pre-Columbian times. When the first Spaniards arrived in the New World in the early 16th century, emeralds were being worshiped, were used in jewelry, and played an important role as sacrificial offerings in ceremonies such as the famous El Dorado ceremony on Lake Guatavita, located just north-east of Bogotá (Bray, 1978). Emeralds were being traded as far south as Peru and Chile and as far north as Mexico. According to Morello (1957), when Spanish conquistador Cortes met the Aztec...

**GEOLOGY OF MUZO AND CHIVOR**

The lower member at Muzo, the Cambiado, consists of highly folded, faulted, and fractured carbonaceous shales and thinly bedded limestones. The Cambiado is discordantly overlain by the Emerald Beds, the latter consisting of thinly bedded, weathered, yellowish-gray shales that have also been intensely folded and invaded by thin calcite veins. The Emerald Beds, as their name implies, contain localized concentrations of emeralds associated with calcite, dolomite, pyrite, quartz, and parsite. Locally, the Cambiado and Emerald Beds are separated by the Cama and the overlying Cenicero. The major difference between these two layers appears to be textural. The Cama consists of an agglomerate of relatively large calcite crystals, whereas the Cenicero, which is usually about a meter thick, consists of small calcite crystals along with pyrite in a carbonate ground mass. Bartic has also been reported in the Cenicero (Oppenheim, 1948).

The Colombian Andes consists of three subparallel ranges: the Western, or Cordillera Occidental; the Central, or Cordillera Central; and the Eastern, or Cordillera Oriental. According to Clements (1941), the Western and Central ranges consist primarily of granites and are best known for their gold deposits (gold production). The Eastern range, however, consists mostly of sedimentary units, principally limestones and shales with minor t masseous and metamorphic rocks exposed only locally. Clements places a Paleozoic age on these crystalline rocks.

The major emerald deposits are limited to the eastern (Chivor) and western (Muzo) margins of the Cordillera Oriental where Cretaceous sediments are well exposed. The geology of the Muzo district has been described by several authors, five of whom are outstanding: Pogue (1916), Lleras (1929), Scheibe (1933), Clements (1941), and Oppenheim (1948). These studies agree that emeralds are restricted to the Villeta formation of Lower Cretaceous age. The Villeta formation consists of a great thickness of intensely folded and fractured black carbonaceous shale and minor limestones. The black shale is so rich in carbon that it is impossible to handle without soiling one's hands. The Lower Cretaceous age of the Villeta has been determined from the presence of fossil ammonites. The highly fractured shales have been invaded by numerous white calcite fracture-filling veins, and it is in these veins that the emeralds occur. Dolomite, quartz, pyrite, and the uncommon rare-earth calcium carbonate, parsite, are accessory minerals commonly found with emerald in these veins. Lleras (1929), Scheibe (1933), and Oppenheim (1948) noted albite as a common vein mineral at Muzo, but Clements (1941) did not observe albite, nor did this author.

The Villeta formation was divided into two members by Lleras (1929), namely, the Cambiado and the overlying Emerald Beds. Locally, these two members are separated by two thin agglomeratic layers of calcite crystals designated the Cama and the Cenicero (Oppenheim, 1948).
emperor Montezuma in Mexico in 1519, the latter was bedecked with fine emeralds. Reportedly, Spanish conqueror Pizarro sent four chests of emeralds from Peru to the King of Spain in 1533. These were all undoubtedly of Colombian origin (Ball, 1931).

Chivor was the first operating emerald mine discovered by the Spaniards in their conquest of the New World. Gonzalo Jiménez de Quesada saw the first sign of emeralds in Colombia at Turquía, Boyacá, in 1537 (Colombian American Business, 1979). Quesada sent Captain Pedro F. de Valenzuela to find the source. That same year, he located the well-developed Chibcha Indian mine of Somos-doco, later to be named Chivor after a nearby valley. Soon thereafter, the Spaniards were vigorously working the Chivor mine using local Indians as slave labor.

Five years after the founding of Santísima Trinidad de los Múzos in 1559 (Wokittel, 1960), the Múzó and Cajira Indian mines were located some 7 km to the west on the Joco Hill. Actual mining of the Múzó area by the Spaniards began in 1567, and initial production is said to have overshadowed production at Chivor (Feininger, 1970). By the end of the 16th century, both Chivor and Múzó were being vigorously worked using Indian slave labor. In 1592, the first recorded grant...
of Chivor was given to Francisco Maldonado de Mendoza by Antonio Gonzalez, president of the New Kingdom of Granada. By this time, however, the treatment of the Indian slaves was so inhuman that on September 22, 1593, President Gonzalez issued a 39-article decree protecting the Indians (Johnson, 1961). This decree was soon followed in 1602 by several royal orders from Phillip III of Spain to enforce the law. By this time, however, the Indian population had already been decimated. As a consequence of this loss of cheap labor and the litigation that followed the royal orders, production of Colombian emeralds declined drastically. In 1650, the Muzo mines were declared royal property, and production further declined. By 1675, the Chivor mine had been abandoned; its location eventually became a mystery that endured for over 200 years. Muzo continued to be worked sporadically throughout the 17th, 18th, and 19th centuries (Barriga and Barriga, 1973) until the government declared it the National Emerald Domain in 1871 (Colombian American Business, 1979). When the mines at Muzo came under government control, production all but ceased and lawless disorder came to characterize the area. This situation has changed only very recently.

Soon after Muzo was placed under government control, the Chivor mine was rediscovered on the basis of a description written almost 300 years earlier. In 1888, Colombian mining engineer Don Francisco Restrepo found a manuscript dating back to the early 17th century in a Dominican convent in Quito, Equador. This manuscript, written by Fray Martin de Aguado, described the location of the Chivor mine as the only place in the Andes where one could see through a pass in the mountains to the plains of the Orinoco. Restrepo's search for the legendary mine ended successfully in 1896. Although legal problems with the government hampered Restrepo's early mining activities, his early 20th century partnership with German mining engineer Fritz Klein coincided with the lifting of some of these restrictions and promising production at the mine. When World War I broke out, however, Klein returned to Germany for military service. Restrepo died at Chivor, and, with Germany's loss of the war, Klein lost all rights to the mine as a result of alien property legislation. In 1919, Chivor was purchased by the Colombian Emerald Syndicate, Ltd., an American company. Since then it has changed hands many times with varying degrees of success, and has been managed by such notable mining engineers as Peter W. Rainier (author of Green Fire, 1942) and Willis Bronkie. The Chivor mines are currently in the hands of the Quintero family.

In 1953, a new mine was discovered 8 km southwest of Chivor at Gachala, reportedly when a woodcutter's mule uncovered an emerald-bearing rock (Anderson, 1955). Although the mine has produced only sporadically since 1953, in 1967 an 858-carat crystal, generally considered one of the finest in existence, was found there. The 5-cm hexagonal prism is known simply as the Gachala emerald and is housed in the Smithsonian Institution (Trapp, 1969).
The terms of the government leases are very demanding. For example, over five years, ESMERALCOL will pay ECOMINAS a total rent of 260 million pesos (about US$6.53 million) plus 5% of the gross production at Coscuez. ESMERALCOL started working Coscuez in March of 1978; by 1979, five bulldozers were working the mine, and a force of 60 National Police patrolled the area to prevent poaching [Colombian American Business, 1975]. The status at Muzo is very similar.

Emerald production statistics for Colombia

Because the main mine area is being stripped away so rapidly, a significant portion of the potential emerald production is lost to the gravels of the Rio Itoco, with the result that an estimated 15,000 guaqueros (independent miners, directly translated as "treasure hunters") mine the riverbed each day (figure 6). These guaqueros usually work alone or in small groups, and they live entirely on what they find. They subsist in nearby rancheros on the flanks of the Itoco Valley, eating pigs, chickens, vegetables, and fruits that they raise or grow locally. Their lifestyle closely resembles that of the miners who joined the mid-19th century California Gold Rush.

Emeralds of Colombia

Figure 6. Looking eastward at guaqueros working in the Rio Itoco below the main mining operations at Muzo.
During the 1970s, as reported by Baskin in the Minerals Yearbook (1979), provide some indication of what has happened to emerald production since the leases were awarded. In 1973, total exports of emeralds from Colombia were reported to be US$2 million. In 1978, these exports rose to US$40 million, and in the first seven months of 1979, exports rose to US$75 million. If this trend continues, Colombia should derive far more revenue from emerald mining than ever in the past.

MARKETING THE EMERALDS

Presently, there are two distinct systems in Colombia for marketing emeralds: (1) the official marketing required by law of the private mining companies under leases from the government, and (2) the illicit marketing done by the guaqueros in the Rio Itoco and, to a lesser extent, at other mines. In the case of the private mining companies, the value of their production is determined by the Controlaría General de la República, representatives of ECOMINAS, and by the owners of the mining companies. The private mining companies then market their emeralds through whichever channels they choose. The amount of emerald mined and subsequent marketing by the guaqueros working in the Rio Itoco below the main mines at Muzo is much more secretive. When a guaquito finds an emerald, eager buyers are waiting on the dirt road next to the river. These esmeralderos, independent emerald dealers from Bogota, gather to buy whatever is found in the river, then take their goods to Bogota to be cut and subsequently traded on the sidewalks off Avenida Jimenez. On any given day, one can see emeralds of any quality and quantity being traded on Avenida Jimenez, ironically, within sight of the Banco de la República.

It is, however, buyer beware when purchasing emeralds on the Avenida Jimenez. Recently, a number of very cleverly enhanced emeralds and “imitations” have been sold to the unwary. These include quartz crystals that have been cored, filled with green plastic, polished, and then glued into a plausible shale matrix; the discreet use of green ink to make moralla, or pale green emerald, appear to be of a fine green color; as well as green glass and plastic imitations.

IMPORTANT COLOMBIAN EMERALDS

Even though emeralds have been mined in Colombia since pre-Columbian times, relatively few very fine large examples are known today. Because of the extremely high value of faceted stones, large emerald crystals are particularly rare. The following is a brief discussion of what many would agree are some of the most important emeralds, both cut and uncut, produced by the Colombian mines.

During the 17th century, large Colombian emeralds were eagerly sought by the Mogul nobility of India. By way of Spain, a great many of the early Colombian stones found a ready market in India through well-established trade routes. One particularly fine example of these emeralds is the “Mogul” (see cover), which is currently owned by private collector Allan Caplan. The Mogul emerald measures 5 cm x 3.8 cm x 3.5 cm and weighs 217.8 cts. (Caplan, 1968). The front of the stone is carved with the floral motif typical of the Mogul carvers, the back contains an Islamic prayer and includes the date 1695 A.D. The drilled stone was probably worn on an article of clothing, perhaps a turban.

Many of these Colombian emeralds were taken from India in 1739 during the sacking of Delhi by the Persians, and now are part of the Crown Jewels of Iran in Tehran. Meen (1969) examined over one thousand of these emeralds and reported that most were over 10 cts. and some exceeded 300 cts. (Meen and Tushingham, 1968). Certainly this collection and the collection in the Topkapi Museum in Istanbul, Turkey, must be considered the two largest collections of Colombian emeralds in the world.

One of the most spectacular pieces of emerald jewelry on public display in the United States is the 300-year-old Spanish Inquisition necklace (see frontispiece), which is in the Smithsonian Institution’s collection. This necklace was reportedly worn in the Spanish and, later, French courts. The drilled hexagonal and cylindrical beads that make up the necklace may very well have originally belonged to articles of pre-Columbian jewelry and were simply reset into this magnificent piece. A 24 mm x 15 mm drilled emerald bead forms the focal point of the necklace; in addition, there are 14 smaller emerald beads averaging 16 mm x 7 mm. Dunn (1975) reports that the necklace also contains over 360 mine-cut diamonds, 16 of which must be considered major items themselves. It is interesting to note that these 16 large diamonds also have been drilled. Another spectacular Colombian emerald in
the Smithsonian collection is the 75-ct. square-cut stone in the Hooker brooch (figure 7). This stone is particularly significant because it lacks the internal flaws that are so typical of large emeralds (Desautels, 1979).

Fine, large emerald crystals are very rare in nature and, because of their inherent value as cut stones, rarely survive intact in the marketplace. There are, however, a few that are worth noting. Reportedly, the finest Colombian crystal in the world is not from Muzo or Chivor, but rather from the recently discovered Gachala mine (figure 8). This fine hexagonal prism weighs 858 cts. and is of unusually fine color and luster. It, too, is part of the gem collection at the Smithsonian Institution (Trapp, 1969).

Several emerald crystals have acquired names through the years. The most famous, perhaps, is the 632-ct. Patricia emerald (figure 9), which was discovered by Justo Daza in December 1920 at the Chivor mine. The Patricia is the largest known emerald from Chivor and was sold early in 1921 for US$60,000. It is interesting to note that Justo received a US$10 bonus for finding the crystal. According to Johnson (1961), the blast that uncovered the Patricia destroyed a pocket that, when examined, contained fragments of an emerald crystal that was probably even larger. The Patricia
was donated to the American Museum of Natural History in the early 1950s. Another named crystal is the famous Devonshire emerald, which was loaned to the British Museum of Natural History in 1936. The current whereabouts of the stone are unknown; the curator of the museum's gem collection recently verified that they have only a wax model. In 1936, the 1384-ct. Devonshire emerald was the largest known emerald from the Muzo mine. Repottedly, the Devonshire is so named because it was given by Pedro I, Emperor of Brazil, to the sixth Duke of Devonshire sometime after 1831, when Pedro I was forced to leave Brazil for Europe. The simple hexagonal prism is approximately 5 cm × 5 cm. It is pictured in Tremayne [1936].

The size and importance of the Patricia and Devonshire emerald crystals is somewhat overshadowed by the collection of unnamed crystals housed in the basement vaults of the Banco de la Republica in Bogotá. This collection consists of five crystals ranging in size from 220 cts. to 1795.85 cts. (figure 10). The finest is an extraordinary 1759-ct. crystal with excellent color and crystal form (figure 11). All of the crystals are reportedly from Muzo and were probably found between 1947 and 1969, when the bank controlled the mines, although their history is not well documented. These crystals are not on public display in Colombia.

The largest known single emerald crystal from Colombia is the 7025-ct. Emilia crystal discovered in 1969. It is reportedly from the Las Cruces mine (near Gachala) and is owned by a private mining concern. It has been displayed at exhibitions around the world, although its current whereabouts are unknown.

There are undoubtedly many other major emeralds in vaults around the world. I have simply presented here a description of some of the better-
known stones. With the increased mining activity at Muzo, it is worth contemplating when the next major emerald will be found, and whether it will be preserved for the public to enjoy.

CONCLUSION
Since the Spanish first started mining emeralds in Colombia in the early 16th century, the two major deposits at Muzo and Chivor have had a chequered history. With the awarding of leases to private concerns in 1977 in the Muzo district, we are seeing what appears to be unprecedented emerald production. At the same time, however, we are also seeing what could be considered reckless mining procedures with the use of dynamite and large numbers of bulldozers. Some reports suggest that these procedures may result in the depletion of the deposit in the very near future. This remains to be seen.

Unfortunately, little detailed work has been done on the geology of the Colombian emerald deposits since the early part of this century. As a result, we have little feel for how extensive the deposits are and what reserves we may expect for the future. Because of the very rugged terrain and dense vegetation and overburden, exploration and mapping are difficult. It is conceivable that these deposits are widespread and that the reserves are actually quite large. Certainly, the presence of what we consider relatively small deposits such as Coscuez near Muzo and Gachala near Chivor suggests that the emerald-bearing units may be equally as widespread, and gives promise of a bright future for Colombian emeralds for some time to come.
